replenishment through either reproduction or human activities such as tree planting, the harvest is not sustainable, and without regulation could result in the extinction or extirpation of species.

A study of the IUCN’s Red List in 2016 showed that 72 percent of species listed as threatened or near-threatened are harvested at a rate that means their numbers cannot be balanced by natural reproduction or regrowth. Some 62 percent of species are at risk from agricultural activity alone, such as livestock farming, tree felling, and the production of crops for food, fuel, fibers, and animal fodder.
