Despite the Urquharts' best efforts, the trail went cold in Texas. Finally, on January 2, 1975, two amateur naturalists, Ken Brugger and Catalina Aguado, discovered the butterflies' wintering site in montane forest north of Mexico City. No tagged monarchs were found, however, and it was not until the following January that the Urquharts found one—tagged by two schoolboys in Minnesota the previous August. Citizen science had provided the hard evidence that the butterflies migrated from North America to Mexico. Now it is known where millions of monarchs spend the winter, the emphasis has changed to tracking their movements each spring and fall. Thousands of people in Mexico, the US, and Canada are helping build an ever clearer picture of what routes the monarch follows and how it deals with changing weather patterns.
