

A pie chart illustrating the sources for the total energy produced and supplied throughout the world in 2023, according to data published by the Energy Institute. “Others” includes traditional biomass, such as wood and dung.

Read accessible description

The future

As growth in renewables increases, the advantages of each type must be balanced against their adverse effects—from biomass pollution to the reported role of wind turbine blades in the deaths of migrating birds. In 2014, the IEA predicted that renewables would provide 40 percent of global energy needs by 2040. In 2024, the IEA further predicted that renewables would account for 41 percent of all world electricity by 2028, with solar and hydropower taking the biggest share. Energy from ocean currents could
