This Egyptian cobra...

...can stretch the ribs in its neck to give itself a dark and scary "hood."

Cobras live in the warm regions of Africa, Asia, and Australia.

The Egyptian

An Egyptian cobra is a highly venomous snake. To defend itself, it raises the front part of its body into this position and shuffles toward the enemy.

Cobras have short fangs at the front of the mouth.

Sand dance

Geckos often find the ground a little too hot in the desert. Their long legs keep the body off the sand, and they lift up their small feet – two at a time – to let them cool.

Web-footed gecko

Thorny devil

This spiked creature likes to spend long periods of time hunting for ants in the hot, open deserts of Australia. During sunlight hours, its body can reach dangerously high temperatures. But, somehow, it copes.

Rain and dew waters flow down the spines and into the mouth as drinking water.
