Branch brigade

If a reptile species is "arboreal," it means that it spends most of its life in trees. Many arboreal reptiles have specially developed features for getting around their chosen habitat.

Superglue geckos

Geckos, like this tokay, are superb climbers. They have small, light bodies and special pads on their feet. The pads are covered in tiny, hairlike hooks that allow them to cling to all kinds of surfaces.

Anchor-tails

Tree snakes have extra-long tails for climbing. The tail coils around a branch and acts as an "anchor" while the snake hauls the rest of its body toward a higher level.

Geckos have five toes, which spread out to provide lots of grip for climbing.

Reptile file

- Arboreal lizards often have sharp claws for climbing tree trunks, as well as special pads for gripping on to silky leaves.
- The giant, or monkey-tailed, skink is the largest of the skink family. It can grow to 26 in (66 cm) in length.
