by more than 250 per cent to the productivity level.[18] The Green Revolution was centred around the use of the High Yielding variety (HYV) of seeds developed by the US agro-scientist Norman Borlaug doing research on a British Rockfellor Foundation Scholarship in Mexico by the early 1960s. The new wheat seeds which he developed *in vivo* claimed to increase its productivity by more than 200 per cent. By 1965, the seeds were successfully tested and were being used by farmers in food deficient countries such as Mexico, Taiwan.

Components of the Green Revolution

The Green Revolution was based on the timely and adequate supply of many inputs/components. The components of the G.R. and a brief introductions follows:-

1. The HYV Seeds

They were popularly called the '***dwarf***' variety of seeds. With the help of repeated mutations, Mr. Borlaug had been able to develop a seed which was raised in its nature of nutrients supplied to the different parts of the wheat plant—against the leaves, stem and in favour of the grain. This made the plant dwarf and the grain heavier—resulting into high yield[19].

These seeds were non-photosynthetic, hence non-dependent on sun rays for targeted yields!

2. The Chemical Fertilizers

The seeds were to increase productivity provided they got sufficient level of nutrients from the land. The level of nutrients they required could not be supplied with the traditional compostes because they have low concentration of nutrients content and required bigger area while sowing—it meant it will be shared by more than one seed! That is why a high concentration fertilizer was required which could be given to the trageted seed only—the only option was the chemical fertilizers—the urea (N), the phosphate (P) and the potash (K).[20]
