noticeable in the Avengers: Infinity War final battle sequence, where Thor's lightning looked more purple than the blue-white shade I expected.

Colours that are less saturated generally fare better. Darker shades looked fairly good, while regular blues, oranges and yellows were well reproduced. So, the issue isn't that the TV gets every colour wrong, but that particularly punchy shades can lose some of their vibrancy or shift slightly in tone.

Black levels are another area where the Nitro falls short. In the submarine sequence from Mission: Impossible – The Final Reckoning, blacks appeared more grey, giving the scene a slightly washed-out look. The TV measured a black level of around 0.6 nits in Calman,

MOTION AND GAMING

MEMC made a noticeable difference when I watched sports. While watching Premier League, camera pans looked smoother with MEMC enabled, and fast players were easier to follow.

The Motion menu also includes Real Cinema, MEMC, HSR and HSR Information, giving you some control over how much processing is applied. I found MEMC more useful for sports than for movies, where some viewers may prefer to keep motion processing lower.

Gaming is one of the better-equipped areas of the Nitro. You get 120Hz support, VRR and ALLM, along with Shadow Detail and Dynamic Black Equalize in the dedicated Game Option menu. ALLM can automatically switch

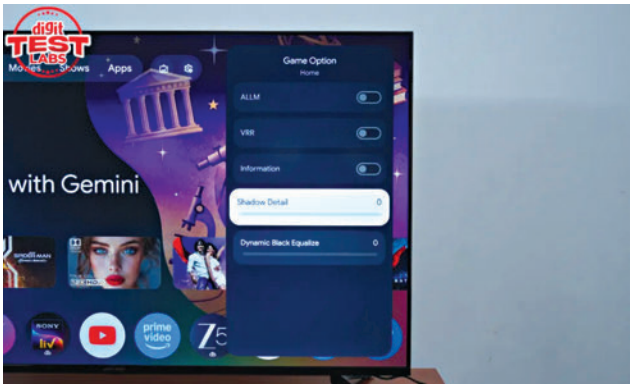

respond while you are moving between different sections.

There's 64GB of storage for apps, while my unit was running the 1 January 2026 Android security patch. A 1.20GB OTA update was also available during testing, which is a good sign that the TV is being kept up to date.

REMOTE

The remote is compact and comfortable to hold, with dedicated hotkeys for popular streaming services. There are quite a few buttons packed into the relatively small body, so some users may find the layout a little cluttered. I was comfortable using it, though.

It connects to the TV over Bluetooth, so you don't need to point it directly

and that elevated black level was noticeable, especially when bright elements appeared alongside them.

HDR support, including Dolby Vision, is useful for compatible content, but the roughly 330-nit brightness limits how impactful HDR highlights can look. Bright elements do stand out more than they would in SDR, but you don't get the same intensity or contrast that brighter Mini LED TVs can deliver.

Overall, the Nitro's picture is at its best with well-lit content and less saturated colours. It produces a sharp 4K image and handles a lot of everyday viewing reasonably well, but the muted saturated colours and elevated blacks are noticeable once you start watching content where colour accuracy and contrast matter more.

the TV into its gaming mode when a compatible source is detected, while VRR helps keep gameplay smoother. The 120Hz support also makes the TV more suitable for gaming than a standard 60Hz panel.

The feature set is certainly there for console gaming, although the final assessment of its gaming performance will come down to input latency and how consistently those features work with different sources.

SOFTWARE EXPERIENCE

The software is based on Google TV, with Android TV 14 underneath, so the interface will feel very familiar to anyone who has used a Google TV device before. Navigation, however, isn't always as quick. Menus can take a moment to

at the screen while using it. The TV also identifies the connected RC-625G remote in its Bluetooth settings, along with information such as its battery level and firmware.

– Vikhyat Rishi

SPECIFICATIONS

Display: 55-inch 4K QLED panel | Refresh Rate: 120 Hz | Viewing angle: 178 degrees | Brightness: 350 nits | Power consumption: 150 Watts | RAM: 2 GB | Storage: 16 GB | Audio: 2 speakers, 2 subwoofers | Ports: 3x HDMI, 2x USB
