1. *Lambda function*—Executes a Python script that sends an HTTP request to your website (e.g., `GET https:/ /cloudonaut.io`) and verifies that the response includes specific text (such as `cloudonaut`).
2. *EventBridge rule*—Triggers the Lambda function every five minutes. This is comparable to the cron service on Linux.
3. *Alarm*—Monitors the number of failed health checks and notifies you via email whenever your website is unavailable.

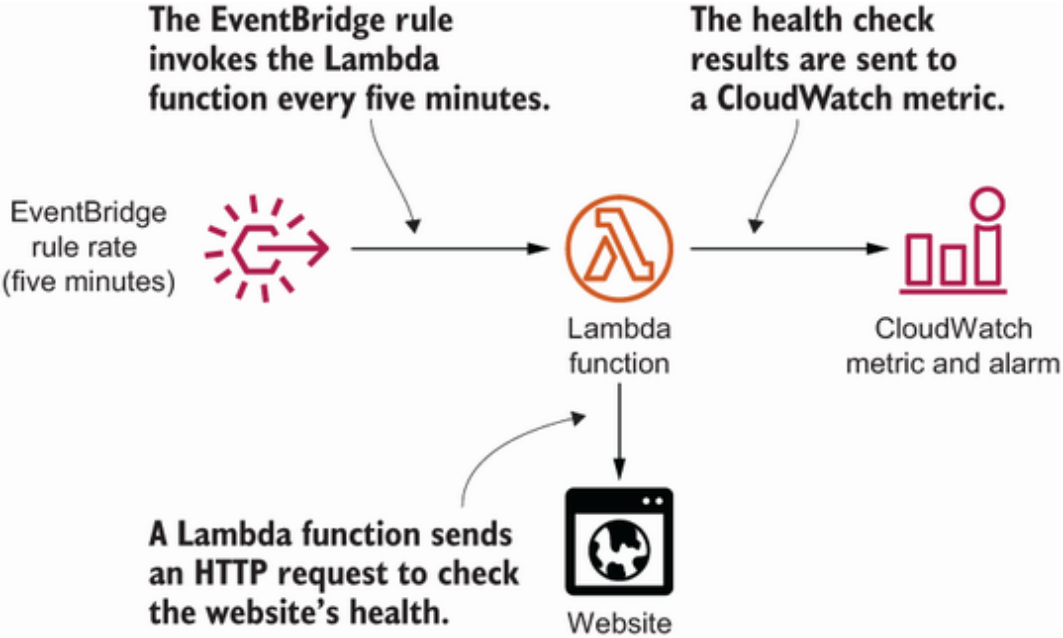

Figure 6.2 The Lambda function performing the website health check is executed every five minutes by a scheduled event. Errors are reported to CloudWatch.

You will use the Management Console to create and configure all the necessary parts manually. In our opinion, this is a simple way to get familiar with AWS Lambda. You will learn how to deploy a Lambda function in an automated way in section 6.3.
