6.3.2 Implementing the Lambda function in Python

Implementing the Lambda function to tag an EC2 instance with the owner's user name is simple. You will need to write no more than 10 lines of Python code. The programming model for a Lambda function depends on the programming language you choose. Although we are using Python in our example, you will be able to apply what you've learned when implementing a Lambda function in C#/.NET Core, Go, Java, JavaScript/Node.js, Python, or Ruby. As shown in the next listing, your function written in Python needs to implement a well-defined structure.

Listing 6.3 Lambda function written in Python

```
def lambda_handler(event, context):    ①
   # Insert your code                  ②
   return                              ③
```

① The name of the Python function, which is referenced by the AWS Lambda as the function handler. The event parameter is used to pass the CloudWatch event, and the context parameter includes runtime information.

② It is your job to implement the function.

③ Use return to end the function execution. It is not useful to hand over a value in this scenario, because the Lambda function is invoked asynchronously by a CloudWatch event.

Where is the code located?
