Multi-AZ with two standby instances

AWS introduced a new option for multi-AZ deployments of RDS databases: Multi-AZ with two standby instances. The advantages compared to the single standby instance that we discussed follow:

1. Both standby instances can be used as read replicas to increase capacity for read-only queries. You will learn more about read replicas later.
2. Lower latency and jitter for transaction commits, which improves the write performance.
3. Faster failover in less than 60 seconds.

Right now, this option is available only for PostgreSQL and MySQL engines. Check out https://aws.amazon.com/rds/features/multi-az/ to learn more.

10.5.1 Enabling high-availability deployment for an RDS database

WARNING Starting a highly available RDS database will incur charges, about USD $0.017000 per hour. See https://aws.amazon.com/rds/pricing/ if you want to find out the current hourly price.

Execute the following command at your local terminal to enable high-availability deployment for the RDS database you started in section 10.1:

```
$ aws cloudformation update-stack --stack-name wordpress --template-url \
➥ https:/ /s3.amazonaws.com/awsinaction-code3/\
➥ chapter10/template-multiaz.yaml \
```
