section 10.1. Replace the `$DBInstanceIdentifier` with the value from `aws rds describe-db-instances --query "DBInstances[0].DBInstanceIdentifier" --output text`:

```
$ aws rds create-db-instance-read-replica \
➥ --db-instance-identifier awsinaction-db-read \
➥ --source-db-instance-identifier $DBInstanceIdentifier
```

RDS automatically triggers the following steps in the background:

1. Creating a snapshot from the source database, also called the primary database instance
2. Launching a new database based on that snapshot
3. Activating replication between the primary and read-replication database instances
4. Creating an endpoint for SQL read requests to the read-replication database instances

After the read-replication database is successfully created, it's available to answer SQL read requests. The application using the SQL database must support the use of read-replication databases. WordPress, for example, doesn't support read replicas by default, but you can use a plug-in called HyperDB to do so; the configuration is tricky, so we'll skip this part. You can get more information here: https://wordpress.org/plugins/hyperdb/. Creating or deleting a read replica doesn't affect the availability of the primary (writable) database instance.

Using read replication to transfer data to another region
