13.2.4 Pitfall: Network interface recovery

Recovering a virtual machine using a CloudWatch alarm in the same availability zone, as described at the beginning of this chapter, is easy because the private IP address and the public IP address stay the same automatically. You can use these IP addresses as an endpoint to access the EC2 instance, even after a failover.

When it comes to creating a virtual network in the cloud (VPC), you need to be aware of the following dependencies, as figure 13.6 illustrates:

- A VPC is always bound to a region.
- A subnet within a VPC is linked to an availability zone.
- A virtual machine is launched into a single subnet.
