the URL from the payload, and uploads the resulting image to an S3 bucket using the unique ID from the payload as the filename.

To complete the example, you need to create an S3 bucket with web hosting enabled. Execute the following command, replacing `$yourname` with your name or nickname to prevent name clashes with other readers (remember that S3 bucket names have to be globally unique across all AWS accounts):

```
$ aws s3 mb s3://url2png-$yourname
```

Now it’s time to create the message queue.

14.2.3 Setting up a message queue

Creating an SQS queue is easy: you only need to specify the name of the queue as follows:

```
$ aws sqs create-queue --queue-name url2png
{
  "QueueUrl": "https:/ /queue.amazonaws.com/878533158213/url2png"
}
```

The returned `QueueUrl` is needed later in the example, so take note of it.

14.2.4 Producing messages programmatically

You now have an SQS queue to send messages to. To produce a message, you need to specify the queue and a payload. You’ll use Node.js in combination with the AWS SDK to make requests to AWS.
