

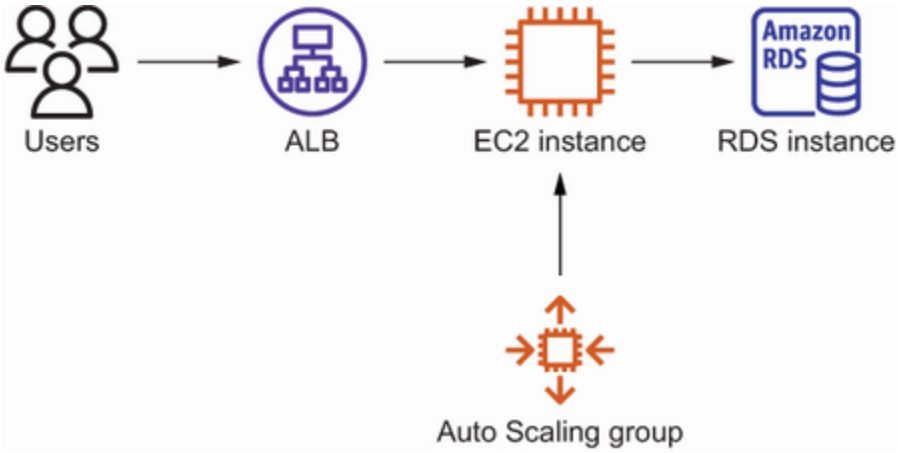

Figure 15.1 Etherpad infrastructure: ALB, EC2 instance, Auto Scaling group, and RDS database instance

Unfortunately, Etherpad does not support clustering, which means it is not possible to run it on more than one machine in parallel.

You are sold on the idea of automating deployments and are looking for the right tool for the job. The first option might sound familiar to you. We are using a solution that applies changes with the help of agents installed on the virtual machines.

15.1 In-place deployment with AWS CodeDeploy

You have two main reasons for performing in-place deployments. First, the speed of the deployment matters. Second, your application persists state on the virtual machine, so you try to avoid replacing running machines. So, for example, if you are running a database-like system that persists data on disk, the in-place deployment approach is a good fit.
