

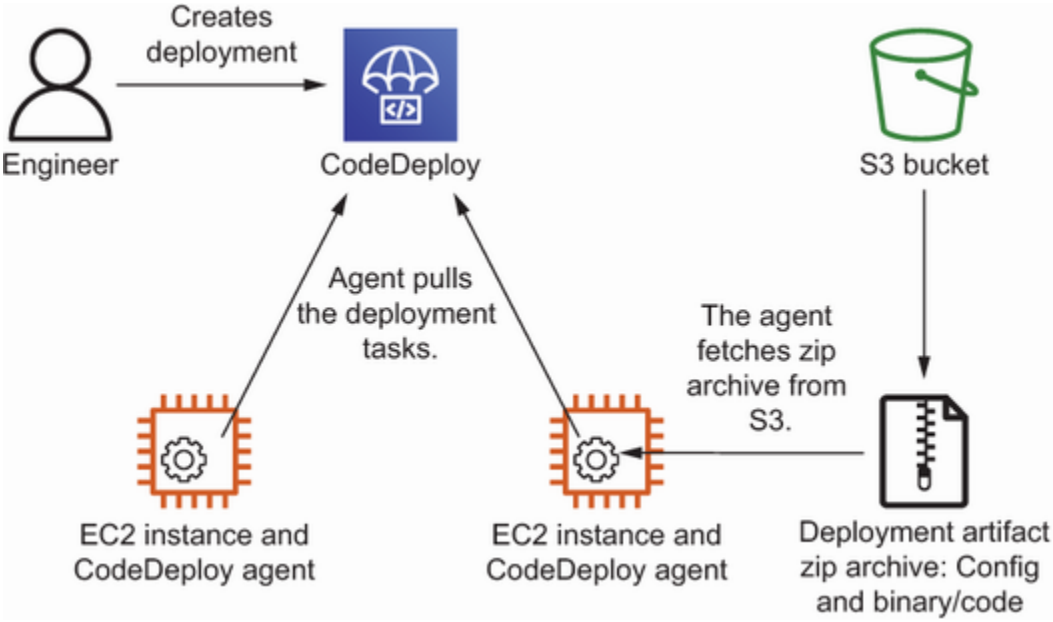

Figure 15.2 CodeDeploy automates deployments to EC2 instances.

This approach is called *in-place deployment*. The EC2 instances keep running while the agent rolls out the change. We want to introduce the following important components of CodeDeploy before we proceed:

- *Application*—Specifies a name and the compute platform (EC2/on-premises, ECS, or Lambda)
- *Deployment group*—Points to the targets (an Auto Scaling group in our example)
- *Revision*—References the code to deploy on S3 or GitHub
- *Deployment*—Rolls out a specific revision to a target group

How do you deploy the web application Etherpad with CodeDeploy? Start with setting up the infrastructure consisting of an Application Load Balancer, an Auto Scaling group, and an RDS database
