instance. We prepared a CloudFormation template to do just this. As usual, you'll find the code in the book's code repository on GitHub: https://github.com/AWSinAction/code3. The CloudFormation template for the WordPress example is located in /chapter15/codedeploy.yaml.

Use the following command to create a CloudFormation stack based on the template. The command will exit after the stack has been created successfully:

```
aws cloudformation deploy --stack-name etherpad-codedeploy \
➥ --template-file chapter15/codedeploy.yaml --capabilities CAPABILITY_IAM
```

Besides creating an Application Load Balancer, an Auto Scaling group, and an RDS database instance, the CloudFormation template also creates the following resources required to deploy Etherpad with CodeDeploy:

- *S3 bucket*—Stores the deployment artifacts (zip files)
- *CodeDeploy application*—Manages deployments of Etherpad
- *CodeDeploy deployment group*—Points to the Auto Scaling group
- *IAM role*—Required by CodeDeploy
- *Parameter*—Stores the database endpoint in the Systems Manager Parameter Store

The next listing shows a deeper look into the resources specified in the CloudFormation template /chapter15/codedeploy.yaml.
