```
➥ --parameter-overrides EtherpadVersion=1.8.18 \
➥ --capabilities CAPABILITY_IAM
```

After updating the CloudFormation stack, reload the Etherpad web application. Check the version, which should be `4b96ff6`.

Congratulations! You have deployed a new version of Etherpad without any downtime for the users. Also, you learned how to use user data to bootstrap an EC2 instance in an automated way.

Cleaning up

Don’t forget to clean up your AWS account before proceeding with the next step as follows:

```
$ aws cloudformation delete-stack --stack-name etherpad-
cloudformation
```

One flaw with launching an EC2 instance from a base image like Amazon Linux 2 and using a user data script to deploy an application is reliability. Many things can and will go wrong when executing the deployment script. For example, GitHub could be down, so the EC2 instance cannot download Etherpad’s source code. The same is true for other repositories, for example, the RPM repository used to install Node.js.

You will learn how to mitigate this risk in the next section by building AMIs, including everything that is needed to start Etherpad without any external dependencies. As an added benefit, this approach
