① References the source; see listing 15.7.

② The shell provisioner executes a script on the temporary build instance.

③ Adds a YUM repository for Node.js

④ Installs Node.js and Git

⑤ Fetches Etherpad from GitHub

⑥ Installs Etherpad dependencies

Before you proceed, make sure to install Packer on your local machine. The following commands install Packer on MacOS with brew:

```
$ brew tap hashicorp/tap
$ brew install hashicorp/tap/packer
```

You can also get the binaries from https://packer.io/downloads.xhtml. Check out http://mng.bz/Zp8a for detailed instructions.

After you have installed Packer successfully, use the following command to initialize the tool:

```
$ packer init chapter15/
```

Next, build an AMI with Etherpad preinstalled like this:

```
$ packer build chapter15/etherpad.pkr.hcl
```

Watch Packer spinning up an EC2 instance, executing the provisioner shell script, stopping the EC2 instance, creating an AMI, and terminating the EC2 instance. At the end of the process, Packer will output the AMI ID, which is `ami-06beed8fa64e7cb68` in the following example:
