⑦ Enabling waiting for a signal from the EC2 instance during a rolling update

⑧ Indicates zero-downtime deployments by ensuring that at least one instance is running during a deployment

To deploy a new version, you need to build a new AMI with Packer and update the CloudFormation stack with the new AMI ID. Before you do, update the Packer template chapter15/etherpad.pkr.hcl and replace Etherpad version `1.8.17` with `1.8.18`, as shown next:

```
$ packer build chapter15/etherpad.pkr.hcl
$ aws cloudformation deploy --stack-name etherpad-packer \
➥ --template-file chapter15/packer.yaml \
➥ --parameter-overrides AMI=$AMI \
➥ --capabilities CAPABILITY_IAM
```

Hurray! You have deployed Etherpad on immutable servers launched from an image built by Packer. This approach is very reliable and allows you to deploy without any downtime. After updating the CloudFormation stack, reload the Etherpad web application. Check the version, which should be `4b96ff6`.
