2. Invalidate the cache because data has changed.
3. Post the link to the blog's Twitter feed.

Let's take a close look at each step.

1. Create a blog post entry in the database

We covered this step earlier by using the title as a primary key. But this time, we use a universally unique identifier (UUID) instead of the title as the primary key. A UUID like `550e8400-e29b-11d4-a716-446655440000` is a random ID that's generated by the client. Because of the nature of a UUID, it's unlikely that two identical UUIDs will be generated. If the client wants to create a blog post, it must send a request to the load balancer containing the UUID, title, and text. The load balancer routes the request to one of the backend servers. The backend server checks whether the primary key already exists. If not, a new record is added to the database. If it exists, the insertion continues. Figure 16.5 shows the flow.
