This means:

- State A is the start state.
- There is a transition possible from state A to B.
- There is a transition possible from state B to C.
- State C is the end state.

But there is no transition possible between (A) → (C) or (B) → (A). With this in mind, we apply the theory to our Imagery example. The Imagery state machine could look like this:

```
(Created) -> (Uploaded) -> (Processed)
```

Once a new process (state machine) is created, the only transition possible is to `Uploaded`. To make this transition happen, you need the S3 key of the uploaded raw image. The transition between `Created → Uploaded` can be defined by the function `uploaded(s3Key)`. Basically, the same is true for the transition `Uploaded → Processed`. This transition can be done with the S3 key of the sepia image: `processed(s3Key)`.

Don’t be confused by the fact that the upload and the image filter processing don’t appear in the state machine. These are the basic actions that happen, but we’re interested only in the results; we don’t track the progress of the actions. The process isn’t aware that 10% of the data has been uploaded or 30% of the image processing is done. It cares only whether the actions are 100% done. You can probably imagine a bunch of other states that could be implemented, but we’re skipping that for the purpose of simplicity in this example: resized and shared are just two examples.
