```
$ aws s3 rm --recursive s3://$bucketname
```

Execute the following command to delete the CloudFormation stack:

```

```

Stack deletion will take some time.

Congratulations! You have accomplished a big milestone: building a fault-tolerant application on AWS. You are only one step away from the end game, which is scaling your application dynamically based on load.

Summary

- Fault tolerance means expecting that failures happen and designing your systems in such a way that they can deal with failure.
- To create a fault-tolerant application, you can use idempotent actions to transfer from one state to the next.
- State shouldn’t reside on the EC2 instance (a stateless server) as a prerequisite for fault tolerance.
- AWS offers fault-tolerant services and gives you all the tools you need to create fault-tolerant systems. EC2 is one of the few services that isn’t fault tolerant right out of the box.
- You can use multiple EC2 instances to eliminate the single point of failure. Redundant EC2 instances in different availability zones, started with an Auto Scaling group, are how to make EC2 fault tolerant.
