

Moving molecules

Water molecules comprise a negatively charged oxygen atom and two positively charged hydrogen atoms. The molecules turn to align with the polarity of the microwaves' electric field. This field changes its polarity billions of times each second, causing the molecules to constantly flip back and forth.

Generating heat
As the water molecules rotate back and forth to align with the changing electric field, they rub against each other, generating heat through friction.

INDUSTRIAL MICROWAVE OVENS

Large microwave ovens are used in industry to dry and cure plastic reinforced with carbon fiber, to remove moisture to create dried foodstuffs, and, in some instances, to vulcanize rubber.
