not only how communities are responding to a range of threats, but the various strategies they have adopted in response. From this starting point, the identification of existing, durable, and safe coping mechanisms with communities can occur, while reducing potentially harmful strategies that leave communities exposed to further risks. Jolliffe (2015) points to how community-level engagement can result in the formulation of localized indicators to measure progress towards security.

A second and broader approach is to promote non-militarized responses. But in encountering the complex nature of landmine use, traditional risk education and information-sharing models need to be re-examined to ensure the safety of populations and enable a secure environment absent of mines for development to occur. A model of mine action needs to be designed that seeks not only to warn populations of dangers, but also responds to the chronic insecurity, for communities to live in sustainable safe and secure environments. Mine action needs to be in coalitions to prevent triggers for landmine use, including "unlawful land grabbing incidents", and the promotion of a "safe and peaceful living environment for communities".[19]

Interim arrangements to diminish landmine use are also important. Chapter six of the NCA includes a number of areas for interim arrangements while political dialogue gets underway, including "projects regarding the health, education and socio-economic development of civilians" (NCA 2015, p. 10). Interim arrangements can also bring the opportunity to build legitimacy, participation, and inclusion of local populations in interim governing authorities, which have the potential to engage local populations on key issues and promote a high level of inclusion that can reduce landmine use more effectively than other measures. Such inclusion will be critical to address the chronic insecurity that has given rise to militarized community approaches, and to promote non-militarized responses to local security concerns.
